

a Heterogeneous population

K subpopulations,
each its own DAG

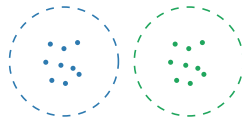

b Single GLOBAL fit

pooled samples
(avg of K subgroups)

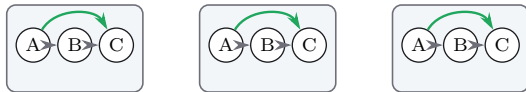

private edge diluted by $1/K$
below threshold → dropped

c Cluster decomposition

K -means partition
into K clusters

d Partition-then-fit

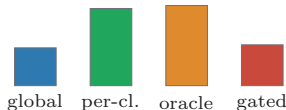

fit within each, merge union
private edges recovered

e Evaluation

F_1 : per-cl. > global

edge count: gated > global

F_1 vs raw edge count
